ONE-PAGE INVESTMENT THESIS · NOVEMBER 2026

Robots that learn on the job.

Robotics is the largest market there is, and nearly all of it sits in places that change: the hotel room, the airport bathroom, the loading dock. Every funded robot model today is a snapshot, frozen before it meets that world. Darwin learns on the job, keeps what it learns, and teaches every other Darwin.

$200B	$75B	1	$10M
a year in US wages in our wedge: janitors, housekeepers, material movers (BLS, approx.)	a year at five million robots, at $15k per robot-year (illustrative)	observation: Darwin learns a new task from one look, performs it, and keeps it	priced seed, raising now; the next round funds the land grab

THE MARKET

Work that is similar but never identical: hotel rooms, airport bathrooms, loading docks. No snapshot can hold it, because a snapshot cannot learn the room it is in. Five million robots worldwide is a $75B toll on the learning network. Operators already pay for narrow autonomy software on OEM bodies, tens of thousands of floor-cleaning robots alone; our wedge is everything those robots cannot do.

WHY IT GROWS FAST

Darwin is sold as software, per robot, on bodies built by OEMs we certify. We integrate the first deployments ourselves, then hand integration to OEMs and customers once it is generic: a learner can be self-serviced; a snapshot cannot. Growth is then gated by how fast we put Darwin on robots, not by data or training; every robot that joins the fleet teaches every other one. No data budget, no retraining cycle, no hardware on our balance sheet: capital goes to deployments, not services.

WHY NOW

The industry committed billions this year to the snapshot path, which funds the gap we win in. Latent video models went open in 2025; Jetson Thor-class compute runs learning on the robot.

THE PRODUCT

Darwin is a foundation model for robots: a JEPA core with a self-learning memory. It ships with general skills we teach it; the customer teaches the job. From one observation Darwin learns a new task, performs it, keeps it, improves with repetition, and shares it with every other Darwin: on the robot, offline, no training cycle.

PROGRESS

Two people and $2M, in twelve months, retired the four risks that decide whether this category exists. March: a JEPA core, trained once on video. May: real time on a Jetson Thor, offline. September: a self-learning memory: one observation, better with repetition, transfers between robots. November: “monkey see, monkey do”, a humanoid copying a human action from one observation, offline. Next: the 1-to-20 learning curve against a fine-tuned VLA. Design partners in automotive, cleaning and manufacturing are scoping trials on the demo.

TEAM

Matt Miesnieks (CEO) co-founded 6D.ai and Mehdi Nikkhah (PhD, CTO) led its AI R&D: on-device vision in 10M+ Pokémon Go clients, sold to Niantic, still the core of Niantic Spatial. Mehdi then built vision teams at Zippin and Instacart.

THE ROUND

$10M priced seed, open to more within 10 to 15% dilution, raising now. Milestone: three to four referenceable design partners by June 2027, which settle price per robot, then a larger round for customer acquisition. Comparable seeds raised $40M to $105M this year; ours buys deployments, not data or retraining.
